THEMA II

Is There a Need to Improve Oral Reproduction?

INTRODUCTION

According to the National Center for Health Statistics, the most common oral health problems are tooth decay and gum disease. These conditions can lead to tooth loss, which can affect an individual's ability to speak, eat, and breathe. Moreover, poor oral health can contribute to systemic problems, such as heart disease and diabetes.

Oral health is an important aspect of overall health. Good oral health can improve one's confidence and ability to socialize. It can also reduce the risk of developing serious health problems.

The need for improved oral reproduction is evident. The World Health Organization (WHO) estimates that over 30% of adults worldwide have some form of dental disease. This includes cavities, gum disease, and missing teeth. In addition, about 10% of adults have lost all of their natural teeth.

This situation is compounded by the fact that many people do not seek treatment for dental problems. This can be due to a lack of insurance, fear of pain, or other factors. As a result, the condition of one's teeth can affect their quality of life.
